

Earthquake Engineering

Dr Tiziana Rossetto

MMM for Marine proposation and a second and a marine and the second seco

Introduction

- In the past 3 centuries over 3 million people have died due to earthquakes and earthquake related disasters.
- The economic losses estimated for the period 1929-1950 are in excess of US\$10 billion.
- 2/3 of the earths crust is seismically active, which means that about 1,000,000,000 people are living in areas of the world that are prone to earthquakes.

Introduction

For more developed countries the economic loss due to an earthquake can be enormous even if the death toll is fairly low (Coburn and Spence 1992):

e.g. Kobe Earthquake (Ms 7.0, Japan, 1995) killed 5,420 people but caused US\$ 150 billion economic loss

University College London <u>UCL</u> Civil & Environmental Engineering

Introduction

For more developed countries the economic loss due to an earthquake can be enormous even if the death toll is fairly low (Coburn and Spence 1992):

e.g. Kobe Earthquake (Ms 7.0, Japan, 1995) killed 5,420 people but caused US\$ 150 billion economic loss

But cost is relative:

e.g. Managua earthquake (Ms 6.1, Nicaragua, 1972), caused 10,000 deaths and US\$ 2 billion economic loss.but This loss = 40% of GNP

Introduction

What do we know?

- Earthquakes cannot be prevented nor accurately predicted.
- It is not ground shaking itself that causes life and economic loss but the collapse or damage of buildings and infrastructure that are too "weak" to resist the ground shaking.

Allower manufally and a second

What is Earthquake Engineering?

The application of civil engineering to reduce life and economic losses due to earthquakes, (i.e to mitigate *seismic risk*)

Mapparan marane marante Maran

What is Seismic Risk from the engineers' perspective?

the probability of losses occurring due to earthquakes within the lifetime of a structure; these losses can include <u>human lives, social</u> and <u>economic</u> <u>disruption</u> as well as material <u>damage</u>.

What is Seismic Risk?

RISK = SEISMIC HAZARD x VULNERABILITY

What is Seismic Risk?

is the probability of the occurrence of damage in a building when exposed to a particular earthquake effect.

RISK = SEISMIC HAZARD x VULNERABILITY

Probability of a potentially damaging earthquake effect occurring at the site of planned construction within its design life.

What is Seismic Risk?

DETERMINED BY MAN: CAN BE REDUCED THROUGH SEISMIC DESIGN

DETERMINED BY NATURE: CANNOT BE REDUCED

and the second second with the second s

Seismic Hazard and Seismic Design

Design Problem: An earthquake usually constitutes the most severe loading to which most civil engineering structures might possibly be subjected, and yet in most parts of the world, even those that are highly seismic, there is a possibility that an earthquake may <u>not</u> occur during the life of the structure.

Note: Lateral loads imposed by winds = 1-3% of building weight. Lateral loads due to earthquakes = 25-30% of building weight.

Seismic Hazard and Seismic Design

Design Problem: An earthquake usually constitutes the most severe loading to which most civil engineering structures might possibly be subjected, and yet in most parts of the world, even those that are highly seismic, there is a possibility that an earthquake may <u>not</u> occur during the life of the structure.

Assessment Problem: Most buildings that exist have <u>not</u> been designed to seismic codes. Can they withstand the type of earthquake that might happen in their location? What will be the damage incurred if an earthquake does occur?

MMM for Man have a second and the second sec

Seismic Hazard and Seismic Design

Hence, engineers require seismic hazard assessments to provide not only a description of the likely seismic loads (ground shaking) to be experienced by an engineering structure, but also to <u>attach probabilities of occurrence to these</u> <u>earthquake loads</u>.

Code-type zonation map

Equivalent Lateral Load

 $V = C.W (\sim F=m.a)$

$$C = \frac{Sa(T_1)}{g}.I.S.q$$

- I = Importance factor
- Sa(T₁) = spectral acceleration for fundamental period, includes site effects
- q = behaviour factor, represents structure's ability to dissipate energy

Conventional Seismic Design

Normal building life assumed to = 50years

Ultimate limit state design: Design a building to resist an earthquake with a return period of 475yrs (i.e. the design loads will have a 10% probability of being exceeded in the structures life).

If a structure is very important (i.e. the consequences of its damage are severe) these loads will be increased: e.g. Nuclear structures designed to resist a 10,000 year return period event.

pharmen ward ward with the more than the second s

Conventional Seismic Design

Normal building life assumed to = 50years

Ultimate limit state design: Design a building to resist an earthquake with a return period of 475yrs (i.e. the design loads will have a 10% probability of being exceeded in the structures life).

If we design for the seismic loads to be resisted by the building without damage (i.e. for the building to react elastically) the cost of construction would be prohibitive

So we design buildings to be damaged under earthquake loading

MMM for Marin marine and marine and marine and the second se

Designing for Controlled Damage

We design buildings to be damaged and react inelastically: meaning they dissipate the same energy, but will undergo greater deformation during the event

Designing for Controlled Damage

We design buildings to be damaged and react inelastically: meaning they dissipate the same energy, but will undergo greater deformation during the event

The location of the damaged areas is controlled to avoid catastrophic failure.

Final Remarks

Damage to buildings is the greatest cause of life loss, direct damage and business interruption in an earthquake.

New buildings should be designed considering earthquake loading with the consequence of their damage in mind during the design process.

Assess our existing structures for their earthquake resistance

Predict the likely loss and intervene with structural strengthening if the risk is too high.
